Keywords: Herbicides, Farm forestry, Christmas trees

Abstract

Good weed control is essential for quality Christmas tree production. Herbicides are usually the most cost-effective way of achieving this. Two principal categories of Christmas tree production can be identified: production in forest plantations and specialist horticultural production. For these two situations, suitable candidate herbicides are identified, and guidance on their safe and effective use is offered.

John Morgan collected and made available useful information on the subject. Mike Lofthouse, Paul Tabbush and Professor Julian Evans made helpful comments on the text. Typing was by Pam Wright.

Front cover: Two-year-old Norway spruce Christmas trees in a well-wooded area on Yattendon Estate, Berkshire. (41642)

#### **1** Introduction

This publication has been written for three reasons:

- good Christmas trees must possess good shape and healthy foliage – this requires, amongst other things, a high standard of weed control;
- Christmas trees are valuable crops and any risk of damage to foliage must be minimized;
- in many situations Christmas tree production is a horticultural activity where special rules apply. These extend the range of herbicides that may be used compared with normal forestry situations.

In common with more conventional tree plantings, weeds compete for moisture, nutrients and light with Christmas trees. Such competition reduces tree growth and survival, and increases the length of time required to produce a merchantable product. Weeds can also detrimentally affect Christmas trees by abrading lower branches, contributing towards the browning and dropping of lower needles, and causing ragged crown growth. All of these traits should be avoided if the intention is to produce a top quality Christmas tree attracting the best sale price. Therefore within Christmas tree plantations, weed control will normally need to take place to a higher standard than in traditional plantations – often 100% weed control for the full 5–8 year rotation is required.

Few herbicide products have specific recommendations for use on Christmas trees. The advice in this publication is based upon experience and trials using herbicides on spruces, pines, and firs, assumed to be the genera of conifers typically grown as Christmas trees. Trials are unlikely to have taken place on the more specialist Christmas tree varieties which are not commonly used for timber production. When considering crop tolerance, field workers should use this publication as a guide to practice, then **test small areas to determine the tolerance of specific conifer species to individual herbicides, before engaging in large-scale treatments.**  i,

#### **2** Types of weed control

The use of herbicides is usually the most cost-effective means of weed control. Alternatives include the use of plastic or organic mulches, cultivation, or the use of less competitive ground cover species, but all of these have their own problems. Mulching effectively prevents weeds establishing, but is expensive - the cheapest effective individual plastic mulches cost around 38p per tree or £950/ha at a stocking of 2500 trees/ha (Deboys, 1994), and are only likely to give effective control for 2-3 years. A continuous sheet mulch is likely to cost around 67–95p per tree, although this would probably reduce to 44p per tree at 10 000 trees/ha (G. Drake-Brockman, personal communication). An effective herbicide regime may cost £50-£250/ha/year, with the majority of the costs being incurred in years 2 and 3. However, any mulch effectively eliminates the ever-present danger of damage to foliage from herbicide applications. Cultivation by itself is unlikely to offer sustained weed control unless it is repeated regularly, which may be a costly and technically difficult option. However, a pre-plant cultivation could be considered to aid mechanical planting, to improve early tree growth and survival, and to provide suitable conditions for soil-acting herbicides to work effectively at minimum rates.

Planting trees through a sown grass sward and then simply mowing grass between the rows with no weed-free bands around the trees can be problematic as moisture stress can occur. The identification of a suitable less competitive ground cover species is still being sought experimentally.

With closely spaced planting designs, the trees themselves will increasingly shade out many weed species. However, total canopy closure may not be desirable as it can cause the death of lower tree branches.

#### **3** Plantation systems

Christmas tree plantations can be conveniently divided into two main types.

#### **Forest plantations**

In conventional forest plantations, early respacing operations may make trees available for sale as Christmas trees. Crops may also be grown specifically as Christmas trees, within a forest block, as part of normal forest production. These trees will come under the forestry definition for herbicide use – users can only apply products with approval for use in forestry situations.

On the more infertile upland sites, a pre-plant application of glyphosate followed by cultivation may give a season or more control of weeds. Thereafter emerging grass and herbaceous weeds should be controlled using conventional forestry weeding regimes. Typically this may involve a directed application of glyphosate, followed by an overall spray of propyzamide in the winter. Willoughby and Dewar (1995) give more information on forestry weed control.

The practice of this form of Christmas tree cultivation involves a relatively low input of resources, giving a lower return from usually poorer quality trees. Attempting this form of management on more fertile lowland restock sites can create problems, as prodigious weed growth can be difficult to control with approved herbicides. Later sections in this Field Book deal with the use of herbicides in horticultural situations – the techniques required for weed control on fertile plantation sites are similar, but fewer products are available for use. This Field Book identifies which herbicide products have full forestry approval. A full list of forestry approved products is given in the Appendix.

#### Horticultural/nursery plantations

Trees established on horticultural or nursery holdings, planted specifically to produce Christmas trees, are regarded as hardy ornamental nursery stock, and therefore come under the long-term off-label arrangements for the use of herbicides (detailed in the Appendix). Any herbicide product with approval for use on any growing crop may be used, as long as all the conditions of use detailed on the label are fulfilled. Applications are made entirely at the user's own commercial risk. Christmas trees grown in a separate fenced-off area within a forest block, where there is no intention of growing trees on to form a final timber crop, could be regarded as being grown on a horticultural holding, provided there is no risk of exposure to the public, to wildlife, or non-target fauna, and there is no risk of run-off to watercourses and surrounding areas.

Specialist growing of Christmas trees in this manner requires higher inputs, but there is also potential for greater returns through the production of top quality trees. Weed control will need to be more intensive, as weed growth is likely to be greater on the more fertile sites that will tend to be chosen for specialist growing. The remainder of this Field Book will deal specifically with weed control in horticultural/nursery production of Christmas trees.

#### 4 Specialist production – weed control regimes

The aim should be to keep a site weed-free at all times, with control of grasses and creeping or climbing herbaceous weeds being the highest priority. Weeding should be seen as a preventive rather than a reactive measure – it is usually far easier to control weeds before they have become established. It is also possible to use cheap, tractor-mounted applications for many pre-emptive weed control treatments, although some directed sprays may be necessary.

A pre-plant spray of a broad spectrum herbicide should be used to kill off any established weeds prior to planting. Any cultivation operations should aim to provide an even, firm, fine tilth across the entire site, for the effective use of soil-acting residual herbicides. Soil-acting herbicides should be applied to weed-free sites in the winter or spring, as an overall application after planting. If weeds start to emerge during the growing season, they will need to be controlled with either directed or overall sprays, depending on the weeds present and hence the products used. At the end of the growing season, established weeds will need to be controlled, again either through directed or overall sprays, prior to the re-application of soil-acting herbicides in the winter/spring. Alternatively, some products exist that may control established weeds and give a degree of residual control in the second year. The post-planting cycle should be repeated for the life of the rotation.

#### **5** Herbicide choice

Tables 1 and 2 summarize some of the most useful herbicides for use in Christmas tree weed control. Only those products with forestry approval can be used for non-specialist production within forests. Tables 3 and 4 give details of specific weed species that each product will control. Where blanks appear in the tables evidence on the specific species is not available. However, broad spectrum products in particular may control a far wider range of species. Guidance on likely weed control spectrums is given in the following sections. Descriptions of individual herbicides are given in the section on herbicide characteristics.

# Notes

Table 2 and the text give essential information on rates and timings for overall or directed applications.

overall application has the potential to cause some distortion or necrosis of foliage. Crop tolerance in this table refers to spruce, pine, and fir genera, and not to specific Christmas tree species. Users are advised to test small areas when using products they are unfamiliar with, In all circumstances, and particularly when using herbicides with foliar activity, directed sprays are the safest means of application. Any prior to making large-scale commercial applications.

- Will tolerate over-spraying provided leader growth has hardened. However, some foliage damage may occur, so it is safest to use directed sprays. Do not treat trees less than 1 m in height. 1 -
- Will tolerate over-spraying at 1.5 I/ha provided leader growth has hardened. Use directed sprays if possible to avoid foliage damage. Directed sprays of up to 5 I/ha may be used. I ŝ
- Use 30–40 kg/ha for trees established less than 2 years after planting. Apply as a directed spot over weeds, around crop trees. I ო
- treated hectare for herbicide only, and do not include the cost of application. Thus if spots or strips around trees are treated instead of the Costs are indicative only, and do not take account of any discounts or extra costs for order size, etc. The costs per hectare shown are per whole area, costs will be considerably less for a gross hectare of woodland. 1 4
- Due to the wide range available, only sample product names are given. Users should contact individual manufacturers for specific costs and conditions of use for their products. For those products that have a full forestry approval, users should refer to the Appendix for a guide to the specific products with the same active ingredients that are approved for use in forestry. I ŝ
- Those products without forestry approval can only be used with Christmas trees grown in horticultural systems, under the long-term off-label arrangements. I ശ
- 7 Use 3 I/ha for small weeds, and 5 I/ha for large deep-rooted species.
- Take particular care when using diuron, and consider alternative treatments, particularly on lighter soils, on poorly established crops and when unfamiliar with the product I ω
- X Unsuitable treatment.
- D✓- Directed sprays only should be used at the rate indicated.
- Suitable herbicide treatment. Products can be sprayed over the crop at the rate indicated (except in pre-planting situations, when no crop is present), however directed sprays are recommended as the safest option.

Key

Moderately susceptible. Moderately resistant. Susceptible. Resistant. T. 

Not tested. e.

Most germinating weeds are likely to be susceptible to dichlobenil. а.

Plants arising from deep-germinating seeds may not be controlled.

Information based upon glasshouse pot trials where activity is likely to be greater than in field conditions.

These results give an indication of likely susceptibility, but should be treated with a degree of caution.

This table lists primarily those weeds detailed on product labels. Some additional information based upon Forestry Commission experimental results is included.

See following page for key to Table 4.

# Key (tor Table 4)

Post-emergent growth stage of weeds (latest at which controlled):

Cotyledon.

сĒ

- Number of expanded true leaves.
  - Diameter or height of weeds.
    - Fully tillered.

- Susceptible at all growth stages.
- Moderately susceptible at all growth stages.
  - Moderately resistant at all growth stages.
    - Resistant.

m

- Not tested.
- All weed susceptible for propyzamide post-emergence are for fully established weeds.
- Control with a programme of an application at 0.5 l/ha followed by one of 1.0 l/ha 3-4 weeks later.
- No specific weeds are listed for glyphosate. It is likely that most species will be controlled by applications of glyphosate at 5.0 l/ha provided they are actively growing.

This table lists only those weed species identified on product labels. It is likely that a wider range of species will be controlled than those listed in the table. No guarantees are made by manufacturers, but the following are likely:

- In addition to the weeds listed, most species will be suppressed by applications of glufosinate ammonium at 5.0 l/ha, or paraquat at 5.5 l/ha, providing they are actively growing, although repeated applications may be required to achieve a total kill of deep-rooted species;
  - 2,4-D + dicamba + triclopyr, 2,4-D, and triclopyr will all control many herbaceous species.

#### **Pre-planting**

Sites may be cleared of perennial weeds by controlling them in a previous crop, or leaving a site fallow then spraying out the weeds when they re-grow. Trees may be planted into bare ground following the desiccation of grass or a crop, or into a cultivated soil.

#### Herbicide options

Products and product mixes based upon:

2,4-D 2,4-D + dicamba + triclopyr Fluroxypyr Glufosinate ammonium Glyphosate Mecoprop (P) Paraquat Triclopyr

#### Pre-flushing residual control on clean sites

Residual soil-acting herbicides should be used to prevent the germination of weed species during the growing season. Application of soil-acting residual herbicides is generally more effective than treating weeds when they emerge. Some residual products offer good crop tolerance and can be sprayed over dormant trees. These herbicides should be applied to clean sites, preferably free of brash and detritus, and which, for the first application after planting, have been cultivated to a firm, fine tilth. Rainfall is required after application to incorporate the herbicides into the soil. A tank mix of products is often used – refer to the weed susceptibility Tables 3 and 4 to pick complementary products covering a wide spectrum of weeds. Aim to apply in spring, **before** bud-burst and weed emergence.

#### Herbicide options

Products and product mixes based upon:

Atrazine Cyanazine Dicamba

ALWAYS READ THE PRODUCT LABEL

Dichlobenil\* Isoxaben Lenacil Metazachlor Napropamide Oxadiazon Pendimethalin Propyzamide Simazine

\* Not in first year after planting.

# Post-flushing control of established weeds and end-of-season clean up

Even with effective applications of soil-acting residual herbicides in the winter and spring, some control of emerging weeds during the growing season may be required. Although some selective products offer fairly good crop tolerance, most broad spectrum herbicides must be applied using directed sprays, to prevent damage to the crop.

Towards the end of the growing season, established weeds should be controlled prior to the application of soil-acting herbicides in the subsequent winter/spring. Some selective products only control weeds of a certain size (see Table 4), and may not therefore be effective at the end of the growing season. Glyphosate may be sprayed over healthy fully dormant trees of most Christmas tree species, but it may be safer to use directed sprays - this also allows the use of higher product rates to control deep-rooted weed species. Weeds must be green and actively growing at the time of spraying, but it should be recognized that control may take many weeks in colder weather conditions. Never add any additive or wetter to glyphosate when making over the top sprays. Triclopyr and 2,4-D can be used over dormant trees of some species to control perennial broadleaved weeds, although again a directed spray would be a safer option. The other non-selective products listed here - paraquat, glufosinate ammonium, and 2,4-D + dicamba + triclopyr - should only be used as directed sprays.

#### Herbicide options

Products and product mixes based upon:

Asulam Clopyralid Cycloxidim 2,4-D 2,4-D + dicamba + triclopyr Fluazifop-p-butyl Fluroxypyr Glufosinate ammonium Glyphosate Mecoprop (P) Pentanochlor Propaquizafop Triclopyr

## Pre-flushing control of established weeds with residual activity

Most sites are cleaned up with an application of foliar-acting herbicide at the end of the growing season, prior to the application of soil-acting herbicides to the bare site in the spring. An alternative is to apply products that will control both established weeds and give residual control into the following growing season.

#### Herbicide options

Dichlobenil Propyzamide

# **6** Herbicide characteristics (for all situations)

Only herbicides with a high level of crop tolerance should be used over poorly planted or stressed trees. Trees are likely to be more susceptible to herbicides in their first growing season. In all situations directed sprays present the safest option. In general, spruces are likely to be more tolerant to herbicide applications than pines, which are in turn likely to be more tolerant than firs.

#### Asulam

Asulam is a foliar-acting translocated herbicide that is effective on bracken and docks.

Crop trees are tolerant of over-spraying, although they may suffer some chlorosis and check in growth if treated when actively growing.

#### Atrazine

Atrazine is a soil-acting residual herbicide, used for the control of germinating annual grasses and broadleaved weeds. At the rates listed in this Field Book, atrazine will have little effect on perennial species. Atrazine has no soil activity in soils with an organic peat layer.

Spraying must take place before tree bud-swell in the spring. Crop trees are tolerant of overall sprays at this stage. Planting can be carried out immediately after treatment but the level of weed control will be reduced if the soil is badly disturbed after spraying.

#### Clopyralid

A foliar-acting herbicide for the control of some mayweed, groundsel and thistles. Spruces and firs will tolerate over-spraying, particularly when young growth has hardened off. Slight twisting of foliage may occur, but this is normally outgrown.

#### Cyanazine

A foliar- and soil-acting herbicide for the control of germinating grass and herbaceous weeds. Small established weeds may be controlled as well as giving some residual control of germinating weeds. Crop trees are tolerant of overall sprays when dormant.

#### Cycloxidim

A foliar-acting translocated herbicide for the control of annual and perennial grasses. Cycloxidim will have no effect on herbaceous species, and crop tolerance is good.

#### 2,4-D

2,4-D is a plant growth regulating herbicide to which many herbaceous species are susceptible. Grasses are unaffected. It is absorbed mainly through the aerial parts of the plant. One week should elapse between treatment and subsequent planting. Norway spruce is moderately tolerant of overall spray providing leader growth has hardened. Other species are less tolerant. Use directed sprays whenever possible.

#### 2,4-D + Dicamba + Triclopyr

A translocated contact herbicide which controls a wide range of annual and perennial herbaceous and woody weeds, but not grasses. Allow 1 month before replanting. All contact with crop trees must be avoided.

#### Dichlobenil

A granular herbicide for use as a spot treatment for perennial broadleaved weeds, particularly docks, nettles, and rosebay willowherb. Grasses will also be controlled. Crop tolerance is variable – use carefully directed applications paying close attention to application rates.

#### Diuron

A highly soluble herbicide for the control of annual grass and herbaceous weeds within established crops. Diuron has been used safely as a directed spray at rates of 2.5 l/ha. Do not use on light textured soils (less than 40% clay). If users are unfamiliar with this product, they should contact a professional adviser before making any applications.

#### Fluazifop-p-butyl

A foliar-acting translocated herbicide for the control of annual and perennial grasses. Fluazifop-*p*-butyl will have no effect on herbaceous species, and crop tolerance is good. It may only be applied through tractor-mounted applicators.

#### Fluroxypyr

A foliar-acting herbicide with good activity on annual broadleaved weeds including cleavers. Some herbaceous weeds including docks are also controlled. Crop trees will be damaged on contact – always use directed sprays.

#### **Glufosinate ammonium**

A non-translocated, foliar-acting herbicide. Glufosinate ammonium controls a broad spectrum of annual and perennial grasses and herbaceous weeds. Gradual chlorosis over the first 2–3 days after spraying is followed by a withering of treated foliage over the next 10–14 days. No translocation to rhizomes or stolons occurs – deeprooted species may require repeat applications for a complete kill. Activity is greatest under warm, moist conditions, when weeds are actively growing. Breakdown of the product is rapid upon contact with the soil. All contact with crop trees must be avoided – always use directed sprays.

#### Glyphosate

A translocated herbicide taken up by the foliage and conveyed to the roots. It causes chlorosis and eventual death of the leaves and then kills roots and shoots. The symptoms usually become apparent about 7 days after treatment, but may take longer to show if vegetation growth is slow.

Glyphosate controls a wide range of weeds including grasses, herbaceous weeds, bracken, heather, and woody weeds. Control of some annual herbaceous weeds, such as cleavers and willowherb, may be variable.

On contact with the soil glyphosate is quickly inactivated. Planting can be carried out 7 days after treatment and a minimum of 7 days should be allowed prior to cultivation breaking up the rhizomes and roots.

Spruce, pine and Caucasian fir (Douglas fir is less tolerant) will tolerate overall sprays of 1.5 I/ha provided leader growth has hardened. Applications should be delayed until October when cold weather is likely to have hardened the crop. Hardening can occur as early as the end of July, or may be delayed until the end of October in some locations and seasons. Contact with crop species in the growing season must be avoided. Directed sprays are safer and allow higher product rates to be used to control deep-rooted weed species.

#### Isoxaben

A soil-acting residual herbicide giving control of germinating herbaceous weeds. Isoxaben will have no effect on grasses or established weeds. Crop tolerance is good.

#### Lenacil

A residual herbicide giving control of a range of germinating herbaceous and grass weed species. Lenacil will have no effect on established weeds. Crop tolerance is good.

#### Mecoprop/Mecoprop (P)

A foliar-acting herbicide for the control of annual herbaceous weeds such as chickweed and cleaver. Perennial herbaceous weeds such as docks, thistles, and nettles will also be controlled or suppressed. Contact with crop foliage should be avoided – always use directed sprays.

#### Metazachlor

A residual herbicide for the control of annual grass and herbaceous weeds. Most activity is pre-emergent, although some post-emergent weed control may be possible depending on the weed species. Crop tolerance is good, although some foliar damage may occur if sprayed on to trees in active growth.

#### Napropamide

A residual soil-acting herbicide for the control of annual grass and herbaceous weeds. Napropamide will have no effect on established weeds. Apply between November and the end of February. Crop tolerance is good.

#### Oxadiazon

A contact and residual herbicide which is particularly effective on perennial bindweed. Crop tree needles are likely to be scorched on contact, particularly after flushing – always use directed sprays.

#### Paraquat

Paraquat is a non-translocated contact herbicide that gives rapid control of a wide range of grass and herbaceous species, and is particularly effective on annual weeds. Deep-rooted species may require repeated applications to give effective control. All contact with crop trees must be avoided – always use directed sprays.

Paraquat is a poison, and can kill if swallowed. Glyphosate and glufosinate ammonium are safer alternative herbicides, however they may be more expensive.

#### Pendimethalin

A residual soil-acting herbicide for the control of annual grasses and annual herbaceous weeds. Pendimethalin will have no effect on established weeds. Crop tolerance is good.

#### Pentanochlor

A foliar- and soil-acting herbicide with some residual activity for the control of some annual grass and herbaceous weeds. Avoid contact with crop - always use directed sprays.

#### Propaquizafop

A foliar-acting translocated herbicide for the control of annual and perennial grasses. Propaquizafop will have no effect on herbaceous species. Crop tolerance is good.

#### Propyzamide

A winter-applied soil-acting herbicide which works most effectively when applied to cold, wet soils. Mild, dry weather can reduce effectiveness. Most grasses, and some herbaceous broadleaved weeds, are susceptible from germination to the true leaf stage, but herbaceous broadleaved weeds which emerge late in the season will only be partially controlled. Established grasses are also controlled. Propyzamide slowly breaks down in the soil, lasting for 3–6 months. Apply liquid formulations from 10 October until 31 December (to 31 January north of a line from Aberystwyth to London), and granular formulations from 10 October until 31 January (28 February in the north). Crop tolerance is good.

#### Simazine

Simazine is a soil-acting residual herbicide, used for the control of germinating annual grasses and broadleaved weeds.

Spraying must take place before tree bud-swell in the spring. Planting can be carried out immediately after treatment but the level of weed control will be reduced if the soil is badly disturbed after spraying.

#### Triclopyr

A plant growth regulating herbicide which is rapidly absorbed, mainly through the foliage, but also by roots and stems. Once inside the plant it is readily translocated. Triclopyr is effective against woody weeds and many perennial herbaceous weeds but not grasses.

Grasses sometimes show some yellowing following spring operations but this is quickly outgrown.

In the soil triclopyr is broken down fairly rapidly by microbial action. Planting should be deferred for at least 6 weeks after application.

Norway spruce may tolerate overall sprays up to 4 l/ha in September through to October provided leader growth has hardened. Aim to use directed sprays if possible.

#### 8 Appendix

#### Long-term off-label arrangements

All applications made under any off-label arrangements are at the user's own risk. This means that the manufacturers cannot be held responsible for any adverse effects on crops or failure to control weeds, but employers and operators still have the responsibility to adhere to on-label instructions when using the product.

In addition to specific off-label approvals, certain fields of use are covered by long-term off-label arrangements, the revised versions of which are valid until 31 December 1999.

- All pesticides with full or provisional label approval for use on any growing crop may be used within forest nurseries, on crops prior to final planting out.
- Christmas trees grown on commercial agricultural and horticultural holdings and in forest nurseries can be regarded as hardy ornamental or forest nursery stock, and hence are covered by the same arrangements.

As well as the usual good working practices required of users, the following **additional** conditions must be complied with when applying pesticides under the long-term off-label arrangements.

- All precautions and statutory conditions of use, which are identified on the product label, must be observed.
- The method of application used must be the same as that listed on the product label, and must comply with relevant codes of practice and requirements under COSHH (The Control of Substances Hazardous to Health Regulations).
- All reasonable precautions must be taken to safeguard wildlife and the environment.
- Products must not be used in or near water unless the label specifically allows such use.

- Aerial applications are not permitted.
- Products approved for use under protection, i.e. under polythene tunnels or glasshouses, cannot be used outside.
- Rodenticides and other vertebrate control agents are not included in these arrangements.
- Use is not permitted on land not intended for cropping for example, paths, roads, around buildings, wild mountainous areas or nature reserves.
- Pesticides classified as hazardous to bees must not be applied when crops or weeds are flowering.
- These extensions of use apply only to label recommendations – no extrapolations are permitted from specific off-label approvals.
- Unless specifically permitted on the product label, hand-held applications are not permitted if the product label:
  - (i) prohibits hand-held use;
  - (ii) requires the use of personal protective clothing when using the pesticide at recommended volume rates;
  - (iii) is classified as 'corrosive', 'very toxic', or has a 'risk of serious damage to eyes'.

If none of the above applies, hand-held application is permitted provided that:

- (i) the concentration of the spray volume does not exceed the maximum recommended on the label;
- (ii) spray quality is at least as coarse as the British Crop Protection Council medium or coarse spray;
- (iii) operators wear a protective coverall, boots, and gloves for applications below waist height – a face shield should be worn in addition for applications above waist height;
- (iv) if the product label gives a buffer zone for vehicle mounted use, a buffer zone of 2 m should be used for hand-held applications.

ALWAYS READ THE PRODUCT LABEL
